

Title of the Invention: Method and Apparatus for Creating Elements and Systems for Description of Position and Motion of Bodies in Three-Dimensional Space to Support Orbital Maneuver Analysis

Inventor: Sergei Tanygin

RELATED APPLICATIONS

This application claims priority from U.S. provisional patent application no. 60/117,183, filed January 26, 1999.

BACKGROUND OF THE INVENTION

1. Field of the Invention

This invention relates to analysis of spacecraft orbits, trajectories, and maneuvers. More specifically, the invention relates to the creation of vectors, axes, points, coordinate systems and other elements, and combinations thereof, to be used in describing the position and motion of objects in space for maneuver planning.

2. Background of the Invention

In the planning and analysis of spacecraft maneuvers, the creation of vectors, axes, points, coordinate systems and other elements and combinations thereof is required in order to describe the position and motion of rigid bodies in three-dimensional space (e.g., spacecraft orbits, trajectories, and maneuvers).

A coordinate system can itself be moving in space. It can also be attached to one or more bodies or be a solely mathematical quantity. Movements of a coordinate system can be described via functions, data files, or user input to a computer program. When a coordinate system must be created, the relationship of the new system to a pre-existing one is defined. There are many ways to define that relationship, but all must include the

1 following: (1) a specification of how the origin of the new coordinate system is translated
2 relative to the origin of the existing system, and (2) a specification of how the set of three
3 orthogonal axes defining the orientation of the new system is rotated relative to the set of
4 axes of the existing system.

5 This introduces two important coordinate concepts that are part of any coordinate
6 system definition: (1) origin point, and (2) axes. Given a point in space (i.e., an "origin")
7 and a set of axes oriented in space, one can create a coordinate system by combining the
8 point and the axes.

9 If there is a plurality of points and axes, one can create any desired combination
10 thereof, thus increasing the number of possible coordinate systems. Advantages of a
11 system providing this capability include: (1) reusability of the coordinate points and axes,
12 of which a limited amount can be used to create a great number of coordinate systems, and
13 (2) improved accuracy where two or more coordinate systems share common points and/or
14 axes, since shared components need only be defined once, thus minimizing the possibility
15 of error in performing duplicative computations.

16 Another component useful in constructing a coordinate system is the vector. The
17 vector relates to points and axes in a number of ways. A new point can be specified by a
18 vector starting at a pre-defined point. A new vector can be defined on the basis of two
19 existing points, starting and ending. A new set of orthogonal axes can be specified by
20 using two non-parallel vectors. A new vector can be created by performing various vector
21 operations (rotation about another vector, cross-product, negation, etc.). Thus, vectors,
22 along with points and axes, provide useful building blocks for constructing new coordinate
23 systems.

1 Existing programs require users to write new computer code whenever a new
2 coordinate relationship is introduced. Alternatively, when a graphical user interface (GUI)
3 is provided, the choices offered by the GUI are limited to a certain subset of the myriad
4 possibilities, thus limiting the options available for the analyst.

5 Some existing programs require that all relationships of interest be hard-coded,
6 whereas some require that only one relationship be hard-coded. For example, the Jet
7 Propulsion Laboratory (JPL) distributes the SPICE toolkit that contains a set of functions
8 to perform coordinate conversions. The conversions can be obtained between any two of
9 the specified coordinate frames, with each new frame specified relative to some existing
10 frame. Nevertheless, this is a laborious task, since the specification must be performed
11 through a file. The JPL SPICE toolkit also lacks the ability to specify points or vectors,
12 which are crucial building blocks for interrelating various coordinate systems.

13 Another existing program, the Navigator software module (a product of Analytical
14 Graphics, Inc. of Malvern, PA), provides a GUI for constructing coordinate systems, but is
15 limited in that it constructs coordinate axes alone. It is not capable of constructing vectors
16 from points nor axes from vectors. Furthermore, the Navigator module cannot construct a
17 coordinate system from a set of axes and a point. Finally, the Navigator module has no
18 capability to account for coordinate systems that rotate with respect to each other.

19 Thus, what is needed is a scheme for a spacecraft maneuver analyst to specify
20 relationships for new coordinate systems without the need to hard-code a software
21 solution. What is also needed is a scheme for a spacecraft maneuver analyst to model
22 orbital maneuver phenomena according to any of a myriad of possible coordinate systems
23 without the need to hard-code a software solution.

SUMMARY OF THE INVENTION

It is an object of the present invention to provide a scheme for a spacecraft maneuver analyst to specify relationships for new coordinate systems without the need to hard-code a software solution. 

It is a further object of the present invention to provide a scheme for a spacecraft maneuver analyst to model orbital maneuver phenomena according to any of a myriad of possible coordinate systems without the need to hard-code a software solution.

It is another object of the present invention to provide a method of creating new spatial objects based on pre-existing parent objects.

It is yet another object of the present invention to provide a computer system that is adapted to create new spatial objects based on pre-existing parent objects.

It is still another object of the present invention to provide a computer program product for enabling a computer system to create new spatial objects based on pre-existing parent objects.

It is a still further object of the present invention to provide a method of creating a desired target object based on a pre-existing parent object and on information explicitly provided by a user.

It is another object of the present invention to provide a computer system that is adapted to create new spatial objects based on a pre-existing parent object and on information explicitly provided by a user.

It is a further object of the present invention to provide a computer program product for enabling a computer system to create new spatial objects based on a pre-existing parent object and on information explicitly provided by a user.

1 Some of the above objects are obtained, according to the present invention, by a
2 method of creating a desired target object based on one or more pre-existing parent
3 objects. The method includes performing a finding operation to find the target object in
4 terms of each of the parent objects, as well as performing a building operation to obtain a
5 combined transformation based on the parent objects. The target object is created by the
6 combined transformation of the parent objects.

7 Others of the above objects are obtained by a computer system implementing this
8 method of creating a desired target object based on one or more pre-existing parent
9 objects. Still others of the above objects are obtained by a computer program product
10 embodying instructions that cause a computer to implement this method of creating a
11 desired target object based on one or more pre-existing parent objects.

12 Certain of the above objects are obtained, according to the present invention, by a
13 method of creating a desired target object based on a pre-existing parent object and on *WHAT INFO?*
14 information explicitly provided by a user. The method includes performing a finding
15 operation to find the target object in terms of the parent object, using the information
16 explicitly provided by the user, to obtain a first transformation, as well as performing a
17 finding operation to find the parent object with respect to the target object, to obtain a
18 second transformation. Additionally, the method includes combining the first and second
19 transformations to create the target object. *INFO?*

20 The present invention provides a GUI and software architecture that empowers the
21 user to create new vectors, axes, points, coordinate systems, and other elements, and
22 combinations thereof. The explicit means of creating coordinate systems and primitives
23 are carried out via user input, imported data from files, or any other means of supplying

1 numerical data to computer programs. In addition to geometrical relationships, coordinate
2 system definitions can describe rates of change in the primitives, thus providing additional
3 ways to create vectors.

5 **DETAILED DESCRIPTION OF THE INVENTION**

6 In one embodiment, the invention relates to the creation of coordinate systems and
7 primitives thereof in the context of a computer program for spacecraft mission analysis,
8 such as the Astrogator module of the Satellite Tool Kit (STK) program developed by
9 Analytical Graphics, Inc. of Malvern, Pennsylvania.

10 The present invention provides a GUI and software architecture that empowers the
11 user to create new vectors, axes, points, coordinate systems, and other elements, and
12 combinations thereof, in the following ways:

- 13 1) specifying a point explicitly relative to an existing coordinate system;
- 14 2) specifying a vector explicitly relative to an existing set of axes;
- 15 3) specifying a set of axes explicitly relative to an existing set of axes;
- 16 4) specifying a coordinate system explicitly relative to an existing coordinate system;
- 17 5) defining a point by an existing vector (i.e., the end point);
- 18 6) defining a vector by two points (i.e., start point and end point);
- 19 7) defining a vector by one or more existing vectors via vector operations (e.g., cross
20 product);
- 21 8) defining a set of coordinate axes by two non-parallel vectors; and
- 22 9) defining a coordinate system as a combination of a point (origin) and a set of
23 coordinate axes.

1 The explicit means of creating coordinate systems and primitives (items 1-4,
2 above) are carried out via user input, imported data from files or any other means of
3 supplying numerical data to computer programs. In addition to geometrical relationships,
4 coordinate system definitions can describe rates of change in the primitives, thus providing
5 additional ways to create vectors:

- 6 a. the rate of change of a vector constitutes another vector;
- 7 b. the rate of change of a point (i.e., its velocity) constitutes a vector; and
- 8 c. the rate of change of axes (rate of rotation or angular rate) constitutes a vector.

9 The present invention gives users the ability to introduce new coordinate primitives
10 by both direct specification through user/file input, and by building them out of existing
11 primitives at run-time through the interface. Coordinate primitives created by both
12 methods can then be reused immediately as building blocks for creating more primitives.
13 The amount of actual coding needed to create a wide range of useful primitives is reduced
14 dramatically compared to conventional systems, creation may be performed at run-time,
15 and manageability of the code is improved since correction made to one of the primitives
16 is automatically inherited by all primitives using this block.

17 While the above description focuses on the use of the invention to create
18 coordinate systems and primitives thereof, it is not intended that the invention be limited
19 to this application. An aspect of the invention is its flexibility in allowing the user to
20 define a variety of elements and combinations thereof for describing the position and
21 movement of bodies in three-dimensional space.

22 Referring to **Figs. 1A-1D**, the basic functional relationships among coordinate
23 system primitives are represented. The function "FindIn" (represented by a double arrow

1 in these Figs.) is a basic function used by the invention to find the object that calls it (i.e.,
2 the point, coordinate system, vector or set of axes in the upper ellipse in each Fig.) in any
3 appropriate existing objects (the lower ellipses).

4 Referring to **Fig. 1A**, a basic functional relationship is illustrated between a point
5 and coordinate system primitives. The basic FindIn function **110** is called by a point
6 object **120** and finds that point object **120** in existing coordinate system objects 1 through
7 N **130**.

8 Referring to **Fig. 1B**, a basic functional relationship is illustrated between a
9 coordinate system and coordinate system primitives. The basic FindIn function **110** is
10 called by a coordinate system object **140** and finds that coordinate system object **140** in
11 existing coordinate system objects 1 through N **130**.

12 Referring to **Fig. 1C**, a basic functional relationship is illustrated between a vector
13 and coordinate system primitives. The basic FindIn function **110** is called by a vector
14 object **150** to find that vector object **150** in existing axes objects 1 through N **160**.

15 Referring to **Fig. 1D**, a basic functional relationship is illustrated between a set of
16 axes and coordinate system primitives. The basic FindIn function **110** is called by an axes
17 object **170** to find that axes object **170** in existing axes objects 1 through N **160**.

18 Referring to **Figs. 2A-2D**, the basic constructional relationships among coordinate
19 system primitives are represented. In these figures, single arrows represent links between
20 pre-existing objects (in the lower ellipses) and the object to be constructed (in the upper
21 ellipse). The double arrows denote required explicit input from the user via the computer
22 program's user interface, a data file, or another source. The words and symbols in square
23 brackets describe the operations that must be performed on the data supplied by the linked

1 objects. It should be noted that there must be a fundamental point and fundamental axes
2 specified directly by the user. These must be defined independently of other objects, since
3 they define the original coordinate system (i.e., the base of the universe). This definition
4 by the user may be explicit, or it may be a tacit adoption of a default universe. 

5 Referring to **Fig. 2A**, basic constructional relationships between a new point **210**
6 and existing coordinate system primitives **214**, **218** are illustrated. In this case, an existing
7 vector **214** is combined with an existing point **218** to define a new point **210** in space. The
8 user provides a link to an existing (parent) coordinate system.

9 Referring to **Fig. 2B**, basic constructional relationships between a new vector **220**
10 and existing coordinate system primitives **224**, **228**, **232**, **236** are illustrated. The new
11 vector **220** may be defined by a vector operation taken on two or more existing vectors
12 **224**, chosen from existing vectors 1 through N **224**. Alternatively, the new vector **220** may
13 be defined by the first derivative of an existing point or vector **228**. As yet another
14 alternative, the new vector **220** may be defined based on the difference between two
15 existing points **232**, **236**. In each case, the user provides a link to an existing (parent) set
16 of axes.

17 Referring to **Fig. 2C**, basic constructional relationships between new axes **240** and
18 existing coordinate system primitives **244**, **248** are illustrated. In this case, two existing
19 vectors **244**, **248** (which should be non-parallel) are aligned to define a new set of axes
20 **240**. The user provides a link to an existing (parent) set of axes.

21 Referring to **Fig. 2D**, basic constructional relationships between a new coordinate
22 system **250** and existing coordinate system primitives **254**, **258** are illustrated. In this case,

1 an existing point 254 and an existing set of axes 258 are assembled to define a new
2 coordinate system 250. The user provides a link to an existing (parent) coordinate system.

3 Referring to **Fig. 3**, a flow chart is shown of a FindIn call according to an
4 embodiment of the present invention. In this case, involving explicit input, the object is
5 first found in its parent object 310, using the explicit information supplied by the user.
6 Then the FindIn function is applied to the parent object 320, and the transformations
7 obtained are combined 330.

8 Referring to **Fig. 4**, a flow chart is shown for the case in which an object is built
9 from pre-existing (or previously constructed) objects. In this case the target object initiates
10 the FindIn function 410 for each of its sub-objects 420, 430. Then the required “building”
11 operation (e.g., refer to the square brackets in Fig. 2) is called 440 to obtain the combined
12 transformation.

13 Referring to **Figs. 5-7**, a simple example is illustrated of an implementation of the
14 invention in the Astrogator program. **Fig. 5** shows the Astrogator Component Browser, in
15 which an available coordinate system (User Defined) has been selected and “cloned” (i.e.,
16 copied). A dialog box called the Astrogator Component Editor allows components of the
17 copied coordinate system to be changed. For example, if the “Axes” field is selected, the
18 selection window shown in **Fig. 6** appears, allowing the user to choose among several
19 alternative sets of axes. Once the new coordinate system is created, it is available in the
20 user interface for all spacecraft mission analysis purposes, such as definition of the initial
21 state of the spacecraft, as shown in **Fig. 7**.

22 The system and method of the present invention operates on a number of standard
23 processors known in the art. UNIX processors such as the Silicon Graphics SGI

1 IMPACT™ and SGI 02™ each with the Reality Engine™ or the Infinite Reality™ engine;
2 the IBM RS6000 with Evans & Sutherland Freedom graphics accelerator; the Hewlett
3 Packard™ HP9000™ with Evans & Sutherland graphics accelerator; the Sun
4 Microsystems SPARC™ station with Evans & Sutherland Freedom graphics accelerator;
5 the Sun Microsystems UltraSUN™ with Creator3D graphics hardware; Digital Equipment
6 Corporation 4D50T and 4D60T processors. Microsoft Windows operating system
7 hardware also can be used with the present invention with MS Windows,
8 Windows95/98/2000, and WindowsNT operating systems with or without OpenGL
9 Accelerators. Generally, all of the above systems should also have 48 MB of memory and
10 at least 75MB of hard drive space available.

11 A system and method for creating elements and systems for description of position
12 and motion of bodies in three-dimensional space to support orbital maneuver analysis has
13 been disclosed. It will be appreciated by those skilled in the art that other variations may
14 be possible without departing from the scope of the invention as disclosed.
